(54) Title: FURAN AND THIOPHENE DERIVATIVES THAT ACTIVATE HUMAN PEROXISOME PROLIFERATOR ACTI-
VATED RECEPTORS

FURAN AND THIOPHENE DERIVATIVES THAT ACTIVATE HUMAN PEROXISOME PROLIFERATOR ACTIVATED RECEPTORS

5 The present invention relates to certain novel compounds. In particular, the present invention relates to compounds that activate human peroxisome proliferator activated receptors ("hPPARs"). The present invention also relates to method for preparing the compounds, their use in medicine, pharmaceutical compositions containing them and methods for the prevention or treatment of PPAR mediated diseases or conditions.

10 Several independent risk factors have been associated with cardiovascular disease. These include hypertension, increased fibrinogen levels, high levels of triglycerides, elevated LDL cholesterol, elevated total cholesterol, and low levels of HDL cholesterol. HMG CoA reductase inhibitors ("statins") are useful for treating conditions characterized by high LDL-c levels.

15 It has been shown that lowering LDL-c is not sufficient for reducing the risk of cardiovascular disease in some patients, particularly those with normal LDL-c levels. This population pool is identified by the independent risk factor of low HDL-c. The increased risk of cardiovascular disease associated with low HDL-c levels has not yet been successfully addressed by drug therapy (i.e. currently

20 there are no drugs on the market that are useful for raising HDL-c). (Bisgaier, C. L.; Pape, M. E. *Curr. Pharm. Des.* 1998, 4, 53-70).

25 Syndrome X (including metabolic syndrome) is loosely defined as a collection of abnormalities including hyperinsulemia, obesity, elevated levels of triglycerides, uric acid, fibrinogen, small dense LDL particles, and plasminogen activator inhibitor 1 (PAI-1), and decreased levels of HDL-c.

30 NIDDM is described as insulin resistance which in turn causes anomalous glucose output and a decrease in glucose uptake by skeletal muscle. These factors eventually lead to impaired glucose tolerance (IGT) and hyperinsulinemia.

35 Peroxisome Proliferator Activated Receptors (PPARs) are ophan receptors belonging to the steroid/retinoid receptor superfamily of ligand-activated transcription factors. See, for example Willson T.M. and Wahli, W.,

Curr. Opin. Chem. Biol. (1997) Vol 1 pp 235-241 and Willson T.M. et. al., J. Med. Chem (2000) Vol 43 p527-549. The binding of agonist ligands to the receptor results in changes in the expression level of MRNA's encloded by PPAR target genes.

5

Three mammalian Peroxisome Proliferator-Activated Receptors have been isolated and termed PPAR-alpha, PPAR-gamma, and PPAR-delta (also known as NUC1 or PPAR-beta). These PPARs regulate expression of target genes by binding to DNA sequence elements, termed PPAR response elements (PPRE). To date, PPRE's have been identified in the enhancers of a number of genes encoding proteins that regulate lipid metabolism suggesting that PPARs play a pivotal role in the adipogenic signaling cascade and lipid homeostasis (H. Keller and W. Wahli, *Trends Endocrin. Metab* 291-296, 4 (1993)).

15

It has now been reported that thiazolidinediones are potent and selective activators of PPAR-gamma and bind directly to the PPAR-gamma receptor (J. M. Lehmann et. al., *J. Biol. Chem.* 12953-12956, 270 (1995)), providing evidence that PPAR-gamma is a possible target for the therapeutic actions of the thiazolidinediones.

20

Activators of the nuclear receptor PPAR γ , for example troglitazone, have been shown in the clinic to enhance insulin-action, reduce serum glucose and have small but significant effects on reducing serum triglyceride levels in patients with Type 2 diabetes. See, for example, D. E. Kelly et al., *Curr. Opin. Endocrinol. Diabetes*, 90-96, 5 (2), (1998); M. D. Johnson et al., *Ann. Pharmacother.*, 337-348, 32 (3), (1997); and M. Leutenegger et al., *Curr. Ther. Res.*, 403-416, 58 (7), (1997).

25

30

The mechanism for this triglyceride lowering effect appears to be predominantly increased clearance of very low density lipoproteins (VLDL) through induction of lipoprotein lipase (LPL) gene expression. See, for example, B. Staels et al., *Arterioscler. Thromb., Vasc. Biol.*, 1756-1764, 17 (9), (1997).

35

Fibrates are a class of drugs which may lower serum triglycerides 20-50%, lower LDLc 10-15%, shift the LDL particle size from the more atherogenic

small dense to normal dense LDL, and increase HDLc 10-15%. Experimental evidence indicates that the effects of fibrates on serum lipids are mediated through activation of PPAR α . See, for example, B. Staels et al., *Curr. Pharm. Des.*, 1-14, 3 (1), (1997). Activation of PPAR α results in transcription of enzymes that increase fatty acid catabolism and decrease de-novo fatty acid synthesis in the liver resulting in decreased triglyceride synthesis and VLDL production/secretion. In addition, PPAR α activation decreases production of apoC-III. Reduction in apoC-III, an inhibitor of LPL activity, increases clearance of VLDL. See, for example, J. Auwerx et al., *Atherosclerosis*, (Shannon, Ire.), S29-S37, 124 (Suppl), (1996).

Certain compounds that activate or otherwise interact with one or more of the PPARs have been implicated in the regulation of triglyceride and cholesterol levels in animal models. See, for example, U.S. Patents 5,847,008 (Doebber et al.) and 5,859,051 (Adams et al.) and PCT publications WO 97/28149 (Leibowitz et al.) and WO99/04815 (Shimokawa et al.). In a recent report (Berger et al., *J. Biol. Chem.* 1999), vol. 274, pp. 6718-6725) it was stated that PPAR δ activation does not appear to modulate glucose or triglyceride levels.

Accordingly, the present invention provides a compound of formula (I) and pharmaceutically acceptable salts, hydrolysable esters and solvates thereof;

As used herein, "a compound of the invention" means a compound of formula (I) or a pharmaceutically acceptable hydrolysable ester or, solvate, thereof.

5

While hydrolyzable esters are included in the scope of this invention, the acids are preferred because the data suggests that while the esters are useful compounds, it may actually be the acids to which they hydrolyze that are the active compounds. Esters that hydrolyze readily can produce the carboxylic acid in the assay conditions or in vivo. Generally the carboxylic acid is active in both the binding and transient transfection assays, while the ester does not usually bind well but is active in the transient transfection assay presumably due to hydrolysis. Preferred hydrolysable esters are C₁₋₆ alkyl esters wherein the alkyl group may be straight chain or branched chain. Methyl or ethyl esters are more preferred.

It will also be appreciated by those skilled in the art that the compounds of the present invention may also be utilized in the form of a pharmaceutically acceptable salt or solvate thereof. The physiologically acceptable salts of the compounds of formula (I) include conventional salts formed from pharmaceutically acceptable inorganic or organic acids or bases as well as quaternary ammonium acid addition salts. More specific examples of suitable acid salts include hydrochloric, hydrobromic, sulfuric, phosphoric, nitric, perchloric, fumaric, acetic, propionic, succinic, glycolic, formic, lactic, maleic, tartaric, citric, palmoic, malonic, hydroxymaleic, phenylacetic, glutamic, benzoic, salicylic, fumaric, toluenesulfonic, methanesulfonic, naphthalene-2-sulfonic, benzenesulfonic hydroxynaphthoic, hydroiodic, malic, steroic, tannic and the like. Other acids such as oxalic, while not in themselves pharmaceutically acceptable, may be useful in the preparation of salts useful as intermediates in obtaining the compounds of the invention and their pharmaceutically acceptable salts. More specific examples of suitable basic salts include sodium, lithium, potassium, magnesium, aluminium, calcium, zinc, N,N'-dibenzylethylenediamine, chloroprocaine, choline, diethanolamine, ethylenediamine, N-methylglucamine and procaine salts. Those skilled in the art of organic chemistry will appreciate that many organic compounds can form complexes with solvents in which they are reacted or from which they are precipitated or crystallized. These complexes are known as "solvents". For example, a complex with water is known as a "hydrate". Solvates of the compound of formula (I) are within the scope of the invention. References hereinafter to a compound according to the invention include both compounds of formula (I) and their pharmaceutically acceptable salts and solvates.

The compounds of the invention and their pharmaceutically acceptable derivatives are conveniently administered in the form of pharmaceutical compositions. Such compositions may conveniently be presented for use in

35

conventional manner in admixture with one or more physiologically acceptable carriers or excipients.

5 While it is possible that compounds of the present invention may be therapeutically administered as the raw chemical, it is preferable to present the active ingredient as a pharmaceutical formulation. The carrier(s) must be "acceptable" in the sense of being compatible with the other ingredients of the formulation and not deleterious to the recipient thereof.

10 Accordingly, the present invention further provides for a pharmaceutical formulation comprising a compound of formula (I) or a pharmaceutically acceptable salt or solvate thereof together with one or more pharmaceutically acceptable carriers therefore and, optionally, other therapeutic and/or prophylactic ingredients.

15 The formulations include those suitable for oral, parenteral (including subcutaneous e.g. by injection or by depot tablet, intradermal, intrathecal, intramuscular e.g. by depot and intravenous), rectal and topical (including dermal, buccal and sublingual) administration although the most suitable route
20 may depend upon for example the condition and disorder of the recipient. The formulations may conveniently be presented in unit dosage form and may be prepared by any of the methods well known in the art of pharmacy. All methods include the step of bringing into association the compounds ("active ingredient") with the carrier which constitutes one or more accessory ingredients. In general
25 the formulations are prepared by uniformly and intimately bringing into association the active ingredient with liquid carriers or finely divided solid carriers or both and then, if necessary, shaping the product into the desired formulation.

30 Formulations suitable for oral administration may be presented as discrete units such as capsules, cachets or tablets (e.g. chewable tablets in particular for paediatric administration) each containing a predetermined amount of the active ingredient; as a powder or granules; as a solution or a suspension in an aqueous liquid or a non-aqueous liquid; or as an oil-in-water liquid emulsion or a water-in-oil liquid emulsion. The active ingredient may also be
35 presented as a bolus, electuary or paste.

A tablet may be made by compression or moulding, optionally with one or more accessory ingredients. Compressed tablets may be prepared by compressing in a suitable machine the active ingredient in a free-flowing form such as a powder or granules, optionally mixed with a other conventional excipients such as binding agents, (for example, syrup, acacia, gelatin, sorbitol, tragacanth, mucilage of starch or polyvinylpyrrolidone), fillers (for example, lactose, sugar, microcrystalline cellulose, maize-starch, calcium phosphate or sorbitol), lubricants (for example, magnesium stearate, stearic acid, talc, polyethylene glycol or silica), disintegrants (for example, potato starch or sodium starch glycollate) or wetting agents, such as sodium lauryl sulfate. Moulded tablets may be made by moulding in a suitable machine a mixture of the powdered compound moistened with an inert liquid diluent. The tablets may optionally be coated or scored and may be formulated so as to provide slow or controlled release of the active ingredient therein. The tablets may be coated according to methods well-known in the art.

Alternatively, the compounds of the present invention may be incorporated into oral liquid preparations such as aqueous or oily suspensions, solutions, emulsions, syrups or elixirs, for example. Moreover, formulations containing these compounds may be presented as a dry product for constitution with water or other suitable vehicle before use. Such liquid preparations may contain conventional additives such as suspending agents such as sorbitol syrup, methyl cellulose, glucose/sugar syrup, gelatin, hydroxyethylcellulose, carboxymethyl cellulose, aluminum stearate gel or hydrogenated edible fats; emulsifying agents such as lecithin, sorbitan mono-oleate or acacia; non-aqueous vehicles (which may include edible oils) such as almond oil, fractionated coconut oil, oily esters, propylene glycol or ethyl alcohol; and preservatives such as methyl or propyl p-hydroxybenzoates or sorbic acid. Such preparations may also be formulated as suppositories, e.g., containing conventional suppository bases such as cocoa butter or other glycerides.

Formulations for parenteral administration include aqueous and non-aqueous sterile injection solutions which may contain anti-oxidants, buffers, bacteriostats and solutes which render the formulation isotonic with the blood of

the intended recipient; and aqueous and non-aqueous sterile suspensions which may include suspending agents and thickening agents.

5 The formulations may be presented in unit-dose or multi-dose containers, for example sealed ampoules and vials, and may be stored in a freeze-dried (lyophilised) condition requiring only the addition of a sterile liquid carrier, for example, water-for-injection, immediately prior to use. Extemporaneous injection solutions and suspensions may be prepared from sterile powders, granules and tablets of the kind previously described.

10

Formulations for rectal administration may be presented as a suppository with the usual carriers such as cocoa butter, hard fat or polyethylene glycol.

15

Formulations for topical administration in the mouth, for example buccally or sublingually, include lozenges comprising the active ingredient in a flavoured basis such as sucrose and acacia or tragacanth, and pastilles comprising the active ingredient in a basis such as gelatin and glycerin or sucrose and acacia.

20

The compounds may also be formulated as depot preparations. Such long acting formulations may be administered by implantation (for example subcutaneously or intramuscularly) or by intramuscular injection. Thus, for example, the compounds may be formulated with suitable polymeric or hydrophobic materials (for example as an emulsion in an acceptable oil) or ion exchange resins, or as sparingly soluble derivatives, for example, as a sparingly soluble salt.

25

30

In addition to the ingredients particularly mentioned above, the formulations may include other agents conventional in the art having regard to the type of formulation in question, for example those suitable for oral administration may include flavouring agents.

35

It will be appreciated by those skilled in the art that reference herein to treatment extends to prophylaxis as well as the treatment of established diseases or symptoms. Moreover, it will be appreciated that the amount of a compound of the invention required for use in treatment will vary with the nature

of the condition being treated and the age and the condition of the patient and will be ultimately at the discretion of the attendant physician or veterinarian. In general, however, doses employed for adult human treatment will typically be in the range of 0.02-5000 mg per day, preferably 1-1500 mg per day. The desired dose may conveniently be presented in a single dose or as divided doses administered at appropriate intervals, for example as two, three, four or more sub-doses per day. The formulations according to the invention may contain between 0.1-99% of the active ingredient, conveniently from 30-95% for tablets and capsules and 3-50% for liquid preparations.

The compound of formula (I) for use in the instant invention may be used in combination with other therapeutic agents for example, statins and/or other lipid lowering drugs for example MTP inhibitors and LDLR upregulators. The compounds of the invention may also be used in combination with antidiabetic agents, e.g. metformin, sulfonylureas and/or PPAR gamma, PPAR alpha or PPAR alpha/gamma agonists (for example thiazolidinediones such as e.g. Pioglitazone and Rosiglitazone). The compounds may also be used in combination with antihypertensive agents such as angiotensin antagonists e.g. telmisartan, calcium channel antagonists e.g. lacidipine and ACE inhibitors e.g. enalapril. The invention thus provides in a further aspect the use of a combination comprising a compound of formula (I) with a further therapeutic agent in the treatment of a hPPAR mediated disease.

When the compounds of formula (I) are used in combination with other therapeutic agents, the compounds may be administered either sequentially or simultaneously by any convenient route.

The combinations referred to above may conveniently be presented for use in the form of a pharmaceutical formulation and thus pharmaceutical formulations comprising a combination as defined above optimally together with a pharmaceutically acceptable carrier or excipient comprise a further aspect of the invention. The individual components of such combinations may be administered either sequentially or simultaneously in separate or combined pharmaceutical formulations.

When combined in the same formulation it will be appreciated that the two compounds must be stable and compatible with each other and the other components of the formulation and may be formulated for administration. When formulated separately they may be provided in any convenient formulation, conveniently in such a manner as are known for such compounds in the art.

When a compound of formula (I) is used in combination with a second therapeutic agent active against the same hPPAR mediated disease, the dose of each compound may differ from that when the compound is used alone. Appropriate doses will be readily appreciated by those skilled in the art.

The compounds of the invention may be prepared by one of the following routes:

(a) Coupling of a thiol or phenol (A) and a heterocyclic methanol (B), by the Mitsunobu reaction (O. Mitsunobu, Synthesis, 1981, 1) or by reaction of the thiol or phenol (A) with a heterocyclic methyl halide (eg chloride) prepared from the methanol (B), followed by hydrolysis of the ester R₁₀

or

5 or a further modification is to use a sulfonyl chloride, which is reduced and coupled *in situ* with a heterocyclic methanol.

10 Intermediates A can be prepared as follows; where $X_2 = \text{SO}_2\text{Cl}$, by direct sulfonation of an aromatic precursor such as commercially available ester C (A.Badawi *et al*, Pharmazie, 1983, 38(12), 838-41). The ester C may also be prepared from commercially available phenol by alkylation with ethyl bromoacetate. Where $X_2 = \text{SH}$ these compounds can be prepared by reduction of the sulfonyl chlorides (H.Uchiro *et al*, Tetrahedron Lett. (1999), 40(16), 3179-3182).

15

23

Where $X_2 = \text{OH}$ a commercially available phenol, such as E, is alkylated, and then reacted with a peracid such as meta chloroperbenzoic acid (mCPBA) to give an acetyl ester which is finally hydrolysed to give the product.

The intermediate alcohols B may be prepared by one of the following general routes:

i) Reduction of a commercially available acid using a reducing agent such as borane:

ii) Bromination of a known/commercially available heterocyclic ester or aldehyde, followed by Suzuki coupling of the resulting bromide with a boronic acid and then reduction:

- iii) The Suzuki coupling of a protected heterocyclic boronate ester, prepared by the orthometallation of a heterocyclic ring with a strong base such as butyllithium followed by quenching with an alkoxyborane, with commercially available aryl bromide followed by subsequent removal of the protecting group, such as a silyl ether.

- iv) Alkylation of heterocyclic aldehydes or ketones using organometallic reagents, the general methods for preparation of which are described elsewhere

vi) Where R_9 is a more complex substituent (not methyl) this can be introduced by reacting a compound in which R_9 is methyl with a brominating agent to give F which can be converted to the desired methanol by one of two methods:

5

by reacting with a nucleophilic group R_{11} (R_{11} can be a thiol, amine, alcohol or an organometallic reagent such as an organocuprate) followed by reduction of the ester gives the desired methanol.

10

(a)

15

by reaction of the bromomethyl group to give a phosphorous reagent (such as a phosphonium salt) and reaction of this with a ketone or aldehyde. Hydrogenation followed by reduction of the ester gives the desired methanol.

20

(i) Introduction of R_9 by directed metallation:

26

(b) Wittig (or related phosphorous reagent chemistry)

5

- 10 When $X_1 = \text{C}$ the bond between X_1 and the adjacent carbon may be single or double – where it is double it is removed in the hydrogenation step.
- Intermediates **H** are prepared by oxidation of the methanols described above.
- Intermediates **G** can be prepared from a compound such as a commercially available ester **C** by treatment with formaldehyde and hydrochloric acid (Org. React. 1942, 1, 303) to give chloride **I** followed by reaction with
- 15 triphenylphosphine.

(c) By reaction of a bromide J with an organometallic reagent such as a boronic acid. There is hydrolysis of a base labile ester during the reaction.

5

Bromides J are prepared by the Mitsunobu reaction as described in section (a) from intermediates A and B, where B is an alcohol synthesized from commercially available starting materials using standard chemical methods.

10

(d) By reaction of an organometallic species (K) with an aryl bromide

15

Intermediate K is prepared as described in section (a), intermediates B are prepared by routes analogous to that described below:

20

A protected aldehyde eg L is reacted with strong base such as n-butyl lithium followed by tributyltin chloride. Hydrolysis, followed by reduction gives the desired alcohol

5

(f) By alkylation of an intermediate N and subsequent hydrolysis

10

preparation of N eg $X_1 = O$; $X_2 = CH_2$

15

20

The alcohol B, prepared from known ester (see above), is converted to the bromide and then to the phosphonate (Org. React., 1951, 6, 273), which reacts with the known benzaldehyde in the presence of base, to give alkene O, reduction using hydrogen over a palladium catalyst gives N.

(g) by reaction of a halide P with a nucleophile reagent such as an amino ester with a palladium catalyst, where $X_1 = \text{NHR}$

Intermediate P can be prepared as described in section (a) starting from a halide such as R

(h) By reaction of an organometallic species (S) with an aryl bromide.

30

Intermediate S can be prepared as shown in the scheme below

5

T can be prepared as outlined in the schemes above by Wittig or related phosphorus chemistry.

Intermediate Y may also be prepared by the following procedure to introduce alkyl groups (R₁₀; R₁₁ = Me); The ketone X is prepared by Friedel-Crafts acylation of the thiophene U with the acid V. X may be dialkylated by using a strong non-nucleophilic base such as sodium hydride followed by quenching the enolate with alkyl iodides. Removal of the methyl ether followed by alkylation with ethyl bromoacetate furnishes ketone Y which may be reduced to the ester Z with triethylsilane and trifluoroacetic acid.

{2-(2-Pyridin-4-ylethyl)-5-[4-(trifluoromethyl)phenyl]-3-furyl}methanol (intermediate 65, 0.59g) was dissolved in dry dichloromethane (4ml), cooled in ice/water bath and treated with thionyl chloride (0.124ml). The reaction was allowed to warm up to room temperature, stirred for 2 hours and then concentrated under reduced pressure. The residue was then dissolved in acetonitrile (4ml) followed by sequential addition of potassium carbonate (0.47g) and ethyl (4-mercapto-2-methylphenoxy)acetate (intermediate 4, 0.46g) and allowed to stir overnight at room temperature. The reaction was concentrated to dryness, partitioned between chloroform/water. The organic layer was dried through a hydrophobic frit, concentrated under reduced pressure and purified using SPE (Si cartridge) using dichloromethane:methanol: "880" ammonia (196:3:1) as eluent to give the *title compound* as a pale brown gum.

The following intermediates and ligands were prepared for the binding and transfection assays described below:

30 (i) **2-{2-methyl-4-[[{4-methyl-2-[4-(trifluoromethyl)phenyl]-1,3-thiazol-5-yl)methyl]sulfanyl]phenoxy}acetic acid.**

This compound was used as a PPARdelta reference in the transfection assays described below and was prepared according to the following method:

Intermediate 1

To a well stirred solution of LiAlH_4 (1.52 g, 40 mmol) in dry THF (50 mL) at 0 °C, was slowly added a solution of ethyl 4-methyl-2-[4-(trifluoromethyl)phenyl]-thiazole-5-carboxylate (12.6 g, 40 mmol) in dry THF (50 mL). The mixture was stirred at room temperature for 2 hs. The reaction was quenched by slow addition at 0 °C of water (2 mL), 5N NaOH (2 mL) and water (6 mL). The precipitate was filtered, washed with EtOAc, MeOH, CH_2Cl_2 and THF. After evaporation, a yellow solid was obtained, that was crystallized from MeOH-water to afford intermediate 1 depicted above (9.90 g, 36 mmol, 90%) as a yellow solid mp 120-122 °C.

To a cold (0°C) stirred solution of intermediate 1 (8.2g, 30 mmol) and Et_3N (6.07 g, 8.36 mL, 60 mmol), in dry CH_2Cl_2 (120 mL) was slowly added MeSO_2Cl (5.49 g, 3.71mL, 48 mmol). After 2 hs at 0°C more Et_3N (6 mmol) and MeSO_2Cl (4.8 mmol) were added. After 2 more h a tlc (hexane:EtOAc, 1:1) showed complete reaction. The reaction mixture was diluted with CH_2Cl_2 (120 mL) and washed with NaHCO_3 (sat.) (2 x 240 mL) and water (2 x 240 mL), dried, filtered and evaporated to afford intermediate 2 (8.0 g, 27 mmol, 90%) as a yellow solid.

Intermediate 3

A mixture of methyl bromoacetate (3.80 g, 2.35 mL, 25.0 mmol), 4-hydroxy-3-methylacetophenone (4.13 g, 27.5 mmol), and Cs_2CO_3 (17.9 g, 55 mmol) in dry acetonitrile (125 mL) was stirred overnight at r.t. The mixture was filtered, washed with acetonitrile, and the solvent evaporated. The remaining syrup was redissolved in EtOAc (400mL), washed with 1N NaOH (3 x 400 mL) and water (2 x 400 mL), dried, filtered, and evaporated to afford the pure title compound (5.50 g, 24.7 mmol, 99%) as a white solid.

Intermediate 4

A solution of Intermediate 3 (5.33 g, 24 mmol), mCPBA (7.25 g, 42 mmol) and p-TsOH (480 mg) in dry dichloromethane (120 mL) was refluxed for 48 h. The reaction mixture was diluted with dichloromethane (120 mL), and successively washed with: aq. KI (2 x 200 mL), NaHSO₃ (2 x 200 mL), dried, filtered and evaporated to afford the title compound (5.0 g, 21 mmol, 87%) as a syrup.

Intermediate 5

A solution of intermediate 4 (4.76 g, 20 mmol) in dry methanol (180 mL) was treated with a 0.5 N solution of NaOCH₃ in MeOH (40 mL, 20 mmol). After 1 h at r.t., the solution was neutralized with 1 N HCl (20 mL). The solvent was evaporated, and the residue partitioned between dichloromethane (300 mL) and water (300 mL). The organic solution was separated, washed with water (300 mL), dried, filtered, and evaporated to afford the title compound (3.3 g, 16.8 mmol, 84%) as a brown solid.

Intermediate 6

Intermediate 2 and intermediate 5 were coupled as in dry acetonitrile (5.0 mL) was stirred overnight at room temperature. The reaction mixture was diluted with CH₂Cl₂ - (50 mL) and water (50mL). The organic phase was separated and further washed with 1N NaOH (2 x 50 mL), and water (3 x 50 mL), dried, filtered, and evaporated to afford the final product (87 %) as brown solid.

2-{2-methyl-4-[(4-methyl-2-[4-(trifluoromethyl)phenyl]-1,3-thiazol-5-yl)methyl]sulfanylphenoxy}acetic acid

Intermediate 6 was hydrolyzed as described below. A solution of the corresponding ester (1 mmol) in THF (10 mL) (in some cases few drops of MeOH were added to help solubility), was treated with 1N LiOH in water (2 mL, 2 mmol), and stirred 16 h at room temperature (when reactions were slow, the temperature was elevated to 50°C). The solution was neutralized with 1N HCl (2 mL, 2 mmol) and the organic solvent evaporated to afford an aqueous solution with an insoluble product. If the insoluble was a solid, it was filtered and dried to afford the final product. If the insoluble was an oil, it was extracted with EtOAc (30 mL). Binding Assay:

Compounds were tested for their ability to bind to hPPAR gamma hPPAR alpha, or PPAR delta using a Scintillation Proximity Assay (SPA). The PPAR ligand binding domain (LBD) was expressed in *E. coli* as polyHis tagged fusion proteins and purified. The LBD was then labeled with biotin and immobilized on streptavidin-modified scintillation proximity beads. The beads were then incubated with a constant amount of the appropriate radioligand (³H-BRL 49653 for PPAR gamma, radiolabelled 2-(4-(2-(2,3-Ditritio-1-heptyl-3-(2,4-difluorophenyl)ureido)ethyl)phenoxy)-2-methylbutanoic acid for hPPAR alpha (see WO 00/08002) and labelled GW 2433 (see Brown, P. J et al . *Chem. Biol.*

1997, 4, 909-918. For the structure and synthesis of this ligand) for PPAR delta) and variable concentrations of test compound, and after equilibration the radioactivity bound to the beads was measured by a scintillation counter. The amount of nonspecific binding, as assessed by control wells containing 50 μ M of the corresponding unlabeled ligand, was subtracted from each data point. For each compound tested, plots of ligand concentration vs. CPM of radioligand bound were constructed and apparent K_i values were estimated from nonlinear least squares fit of the data assuming simple competitive binding. The details of this assay have been reported elsewhere (see, Blanchard, S. G. et. al. Development of a Scintillation Proximity Assay for Peroxisome Proliferator-Activated Receptor gamma Ligand Binding Domain. *Anal. Biochem.* 1998, 257, 112-119).

Transfection assay:

Compounds were screened for functional potency in transient transfection assays in CV-1 cells for their ability to activate the PPAR subtypes (transactivation assay). A previously established chimeric receptor system was utilized to allow comparison of the relative transcriptional activity of the receptor subtypes on the same target gene and to prevent endogenous receptor activation from complicating the interpretation of results. See, for example, Lehmann, J. M.; Moore, L. B.; Smith-Oliver, T. A.; Wilkison, W. O.; Willson, T. M.; Klierer, S. A., An antidiabetic thiazolidinedione is a high affinity ligand for peroxisome proliferator-activated receptor γ (PPAR γ), *J. Biol. Chem.*, 1995, 270, 12953-6. The ligand binding domains for murine and human PPAR alpha, PPAR gamma, and PPAR delta were each fused to the yeast transcription factor GAL4 DNA binding domain. CV-1 cells were transiently transfected with expression vectors for the respective PPAR chimera along with a reporter construct containing five copies of the GAL4 DNA binding site driving expression of secreted placental alkaline phosphatase (SPAP) and β -galactosidase. After 16 h, the medium was exchanged to DME medium supplemented with 10% delipidated fetal calf serum and the test compound at the appropriate concentration. After an additional 24 h, cell extracts were prepared and assayed for alkaline phosphatase and β -galactosidase activity. Alkaline phosphatase activity was corrected for transfection efficiency using the β -galactosidase

activity as an internal standard (see, for example, Kliewer, S. A., et. al. *Cell* 83, 813-819 (1995)). Rosiglitazone (BRL 49653) was used as a positive control in the hPPAR gamma assay. The positive control in the hPPAR alpha assays was 2-methyl-2-[4-[[[4-methyl-2-[4-trifluoromethylphenyl]-thiazol-5-yl-carbonyl)amino]methyl]-phenoxy]propionic acid. The positive control for PPAR delta assays was 2-[2-methyl-4-[[[4-methyl-2-(trifluoromethyl)phenyl]-1,3-thiazol-5-yl]methyl)sulfanyl]phenoxy}acetic acid.
